

React 2

Output

SME

1. React Components

React components are reusable and independent pieces of a user interface. They help divide an application into smaller, manageable parts, making the code easier to develop and maintain.

2. Difference Between Components and JavaScript Functions

A React component is a JavaScript function or class that returns JSX to display UI elements. A regular JavaScript function performs general tasks and returns any type of value, not necessarily UI.

3. Types of Components

React has two main types of components: **Functional Components** and **Class Components**. Functional components are simpler and are preferred in modern React, while class components are mainly used in older React applications.

4. Class Component

A class component is created using an ES6 class that extends `React.Component`. It uses a `render()` method to display UI and can manage state and lifecycle methods.

5. Functional Component

A functional component is a simple JavaScript function that returns JSX. It is easier to write, supports Hooks like `useState`, and is the recommended way to create components in modern React.

6. Component Constructor

A constructor is a special method used only in class components. It initializes the component's state and performs setup tasks before the component is rendered.

7. `render()` Function

The `render()` function is a required method in class components that returns the JSX to be displayed on the screen. React calls this method whenever the component needs to update its UI.
