

React 3

Output

Objectives

1. React Components

React components are reusable, independent pieces of UI that return JSX. They help organize code and make applications easier to build and maintain.

2. Difference Between Components and JavaScript Functions

A JavaScript function performs a specific task and returns a value. A React component is a special function (or class) that returns JSX to render UI and can accept props.

3. Types of Components

React has two main types of components: **Class Components** and **Function Components**. Function components are simpler and are the preferred approach in modern React.

4. Class Component

A class component is created using the class keyword and extends `React.Component`. It can manage state, use lifecycle methods, and must include a `render()` method.

5. Function Component

A function component is a JavaScript function that returns JSX. It is simpler, easier to read, and can use Hooks like `useState` and `useEffect`.

6. Component Constructor

The constructor is a special method in a class component used to initialize state and bind methods. It is called automatically when the component is created.

7. `render()` Function

The `render()` function is a required method in class components that returns the JSX to be displayed on the screen. It is called whenever the component needs to update its UI.
