Objectives

1. Explain the Need and Benefits of Component Life Cycle

The **component life cycle** defines the different stages a React component goes through from creation to removal. It allows developers to execute code at specific points, such as fetching data, updating the UI, or cleaning up resources. Using lifecycle methods improves performance, code organization, and resource management.

2. Identify Various Life Cycle Hook Methods

The main lifecycle methods in React class components are:

- **Mounting:** constructor(), render(), componentDidMount()
- **Updating:** shouldComponentUpdate(), render(), componentDidUpdate()
- **Unmounting:** componentWillUnmount()

3. List the Sequence of Steps in Rendering a Component

The rendering process follows this sequence:

1. **Constructor** – Initializes state and binds methods.
2. **Render** – Creates and returns the JSX/UI.
3. **ComponentDidMount** – Executes after the component is added to the DOM.
4. **Update Phase** (when state/props change) – shouldComponentUpdate() → render() → componentDidUpdate().
5. **ComponentWillUnmount** – Runs just before the component is removed from the DOM.
